Key messages:

- In 2010, 79 percent of households surveyed in Burkina Faso reported unsafe disposal of the feces of their youngest child under age three.
- Even among households with improved toilets or latrines, 32 percent reported unsafe child feces disposal behavior.
- Urban households were 7 times more likely to safely dispose of their children’s feces than rural households (73 percent versus 10 percent).1

OVERVIEW

Safe disposal of children’s feces is as essential as the safe disposal of adults’ feces. This brief provides an overview of the available data on child feces disposal in Burkina Faso and concludes with ideas to strengthen safe disposal practices, based on emerging good practice.

The Joint Monitoring Programme for Water Supply and Sanitation (JMP) tracks progress toward the Millennium Development Goal 7 target to halve, by 2015, the proportion of people without sustainable access to safe drinking water and basic sanitation. The JMP standardized definition for an improved sanitation facility is one that hygienically separates human excreta from human contact.2

In the latest JMP report, only 19 percent of Burkina Faso’s population had access to improved sanitation in 2012.1 This means that 13.4 million individuals in Burkina Faso lacked improved sanitation in 2012, of which 9.3 million practice open defecation. However, these estimates are based on the household’s primary sanitation facility, and may overlook the sanitation practices of young children. In many cases, children may not be able to use an improved toilet or latrine—because of their age and stage of physical development or the safety concerns of their caregivers—even if their household has access to one.

SUMMARY OF CHILD FECES DISPOSAL DATA

In Burkina Faso in 2010, less than a quarter (22 percent) of households reported that the feces of their youngest child under age three were safely disposed. Only 9 percent of households reported that their youngest child’s feces were disposed of into an improved sanitation facility, according to the 2010 Demographic and Health Survey (DHS) (see Figure 1). This low percentage of households reporting improved child feces disposal suggests that children under age three have worse sanitation than the country’s broader population, where 19 percent use improved sanitation. Interestingly, a majority of households (62 percent) reported throwing children’s feces into the garbage. Because of variable solid waste management systems and environmental health concerns such as leeching, this is considered an unsafe practice.4

Households lacking improved sanitation, those in rural areas, and poorer households—as well as households with younger children—have a higher prevalence of unsafe disposal of child feces. Between 2003 and 2010, overall reported safe disposal of child feces remained approximately the same, but was substantially higher in urban areas (see Figure 2).

Households practicing open defecation reported the highest level of unsafe child feces disposal, at 98 percent (see Figure 3). For these households practicing open defecation (i.e., they do not use a latrine), 2 percent reported safe child feces disposal. It is possible, but not probable, that households that do not use a latrine themselves deposit their children’s feces into a latrine.

A slight shift in safe disposal practices is also seen as children grow (see Figure 4): only 20 percent of households with children under one year old report safe disposal, compared to 31 percent of households

What Is “Safe Disposal” of a Child’s Feces?

The safest way to dispose of a child’s feces is to help the child use a toilet or latrine or, for very young children, to put or rinse their feces into a toilet or latrine. For the purposes of this brief, these disposal methods are referred to as “safe,” whereas other methods are considered “unsafe.” By definition, “safe disposal” is only possible where there is access to a toilet or latrine. When a child’s feces is put or rinsed into an “improved” toilet or latrine, this is termed “improved child feces disposal.”
FIGURE 1 The prevalence of safe disposal is low and improved disposal even lower. In 2010, 11 percent of households left their child’s feces in the open. Percentage of households reporting each feces disposal practice for their youngest child under age three, Burkina Faso, 2010.

FIGURE 2 The prevalence of safe child feces disposal has stagnated over time, but remains more than seven times higher in urban than in rural areas. Percentage of households reporting safe feces disposal for their youngest child under age three, by urban and rural residence, Burkina Faso, 2003 and 2010.6

FIGURE 3 Even among households with improved sanitation, only two-thirds (68 percent) reported safe child feces disposal. Reported feces disposal practice for household’s youngest child under age 3, by household sanitation facility type, Burkina Faso, 2010.

with children who are four years old. Although safe disposal increases slightly with the age of the child, use of a toilet/latrine is fairly limited and only reaches 5 percent for children age four. The feces of the oldest children are also the most likely to be left in the open (27 percent), which is essentially open defecation. At these young ages, the behavior of the child’s caregiver is critical to dispose of their feces safely and shape the child’s toilet training.

Safe disposal differs widely across the wealth asset quintiles. The poorest three quintiles of households are substantially less likely than the richer and richest households to report safe child feces disposal; only 2–9 percent of the poorest three quintiles report safe disposal (see Figure 5). The feces of 14 percent of children in the poorest three quintiles of households were left in the open—equivalent to open defecation. Looking at overall sanitation facility coverage for households with children under age three in Burkina Faso, less than 1 percent of the poorest households reported use of any toilet/latrine (improved, shared, or unimproved), compared to 94 percent of the richest quintile. This is an important factor in children’s feces disposal: by definition, safe disposal is only possible when there is access to a toilet/latrine.

Behind this national-level data, there is wide variation in child feces disposal practices, with a greater prevalence of unsafe practices among households without access to improved sanitation, in rural areas, and those that are poorer. For example, unsafe disposal in
child defecates that matters but how the mother then deals with it. “12 have included messaging on safe disposal of children’s feces, and

IDEAS FOR CONSIDERATION

households with the youngest children and no sanitation facility

show even greater extremes of disparity—with the poorest rural

areas and among the poorest 60 percent of households is worse

than among children overall. Although this brief only focuses on one

socioeconomic indicator at a time, applying multiple lenses would

show even greater extremes of disparity—with the poorest rural

households with the youngest children and no sanitation facility

likely reporting the greatest prevalence of unsafe disposal.

What Is the Impact of Unsafe Disposal of Child Feces?

There is widespread belief that the feces of infants and young

children are not harmful, but this is untrue. In fact, there is
evidence that children’s feces could be more risky than adult

feces, due to a higher prevalence of diarrhea and pathogens—
such as hepatitis A, rotavirus, and E. coli—in children than in

adults.7 Therefore, children’s feces should be treated with the

same concern as adult feces, using safe disposal methods

that ensure separation from human contact and household

contamination.

In particular, the unsafe disposal of children’s feces may be

an important contaminant in household environments, posing

a high risk of exposure to young infants.8 Poor sanitation can

result in substantial health impacts in children, including a

higher prevalence of diarrheal disease, intestinal worms,

enteropathy, malnutrition, and death. According to the World

Health Organization (WHO), most diarrheal deaths in the

world (88 percent) are caused by unsafe water, sanitation,
or hygiene. More than 99 percent of these deaths are in
developing countries, and about eight in every 10 deaths are

children.9 Diarrhea obliges households to spend significant

sums on medicine, transportation, health facility fees, and

more, and can mean lost work, wages, and productivity

among working household members.10 Stunting and worm

infestation can reduce children’s intellectual capacity, which

affects productivity later in life. The WHO estimates that the

average IQ loss per worm infection is around 3.75 points.11

a neglected area of policy and program intervention in the country.

Given the relatively few programs focusing on children’s sanitation

in Burkina Faso and globally, there is not a strong evidence base of
effective strategies for increasing the safe disposal of children’s feces.

Significant knowledge gaps must be filled before comprehensive,
practical evidence-based policy and program guidance will be
available. Nevertheless, organizations and governments interested in
improving the management of children’s feces could consider:

• Conducting formative research to understand the behavioral

drivers and barriers to safe child feces disposal

• Strengthening efforts to change the behavior of caregivers through

programs that encourage cleaning children after defecation, potty

training children, and using appropriate methods to transport

feces to a toilet/latrine, as well as handwashing with soap after fecal

contact and before preparing food or feeding a child

• Exploring opportunities to integrate child sanitation into existing

interventions that target caregivers of young children, such as

including key messages in antenatal/newborn care materials and

infant and young child feeding guidance provided to parents,

ensuring that midwives’ training includes information on safe child

feces disposal, and integrating child sanitation information into

early childhood development materials and preschool programs

• Partnering with the private sector to improve feces management

tools, such as potties, diapers, tools for retrofitting latrines for

child use, and scoopers

• Improving the enabling environment for management of

children’s feces, by including specific child feces related criteria in

open defecation free (ODF) verification protocols and in national

sanitation policies, strategies, or monitoring mechanisms.

 IDEAS FOR CONSIDERATION

In the past, some hygiene promotion programs in Burkina Faso
have included messaging on safe disposal of children’s feces, and
some interesting research was done that showed: “it is not where
the child defecates that matters but how the mother then deals with it.”12 However, in general, sanitation for children under age three has been
Opportunities to integrate child sanitation into existing interventions that target caregivers of young children could be explored when appropriate.

DATA SOURCES

Unless otherwise specified, all analysis in this brief is based on child feces disposal behavior self-reported by the child’s mother or caregiver in the 2010 Burkina Faso Demographic and Health Survey (DHS), which is the latest Multiple Indicator Cluster Survey (MICS) or DHS available for Burkina Faso that records child feces disposal behaviors.

The MICS and DHS collect data in a generally harmonized manner and hence are the basis for this country profile series. However, whereas the DHS collects data on the youngest child under age five living with the mother for each household, the MICS collects data on all children under age three who live with the respondent (mother or caretaker). To maximize comparability, we restricted all analysis to children under age three in all figures, except Figure 4.

It is likely that self-reports overestimate safe disposal. Comparing self-reported behavior with structured observations found there was a tendency to over-report practices perceived as “good,” e.g., the child used a potty (75 percent reported vs. 66 percent observed) or feces found there was a tendency to over-report practices perceived as “good,” e.g., the child used a potty (75 percent reported vs. 66 percent observed). Regardless of this issue, self-reports are currently regarded as the most efficient method for gauging safe disposal of children’s feces.

REFERENCES

2 The JMP has established a set of standardized definitions to categorize improved sanitation, which are used to track progress toward Millennium Development Goal 7. However, these definitions are not always the same as those used by national governments. See Progress on Drinking Water and Sanitation: Update 2014.
6 The wealth indices used to classify households into wealth quintiles include drinking water and sanitation variables.

NOTES

We’re interested in your thoughts. Have you found different evidence of what works through your own programming? If you have thoughts to share, or know of a program that is encouraging the safe disposal of child feces, please contact WSP at worldbankwater@worldbank.org or UNICEF at WASH@unicef.org so that we can integrate your information into future program guidance.
